Overview

Serial API allows external application or device to communicate with the SimpleBGC controller via UART port. Each controller has one or more UART ports that can be used to send and receive Serial API commands. Commands may be used to retrieve actual system state and realtime data, change settings, control gimbal, trigger pin state, execute various actions, get access to internal EEPROM and I2C bus, and so on. Moreover, SimpleBGC GUI software uses the same Serial API to communicate with the board, so all of its functions may be implemented in third-party applications.

Message format

Communications is initiated from the GUI side (host) by sending *outgoing* commands. The controller board may do some action and send response (further named as *incoming* commands). Each command consists of the *header* and the *body*, both with checksum. Commands with the wrong header or body checksum, or with the body size that differs from expected, should be ignored.

Board can work on different serial baud rate, so the GUI should find proper baud rate by sending CMD_BOARD_INFO command on every speed and wait for response, until valid response is received.

32bit boards with firmware version 2.40, works only with parity=EVEN COM-port setting. Starting from 2.41, both EVEN and NONE parity are supported (NONE is default, and EVEN is detected automatically). So beside baud rates, host should vary parity setting when connecting to boards ver.>3.0

Make a small delay after sending each command to prevent overflow of the input buffer. Delay should be about 10-20 ms, and depends on the size of the request and response. If new serial data comes when the input buffer is full, whole message will be lost. There is also a control of overflow of the output buffer on the board's side: if it have to write an answer to the output buffer, it hangs until buffer will have enough space to accept new data. If requests comes with too big rate, it may negatively affect normal operation of the board and impact stabilization.

Input and output commands have the same format, described below:

Header:

character '>'
command ID - 1u
data_size – 1u, may be zero
header checksum = (command ID + data_size) modulo 256 - 1u

Body:

[array of bytes *data_size* length]
body checksum - 1u

Checksum is calculated as a sum of all bytes modulo 256.

Example: outgoing command to read Profile2:

0x3E (>)	0x52 (R)	0x01	0x53	0x01	0x01
	command id	data size	header checksum	data	body checksum
header				body	

Data type notation

- 1u – 1 byte unsigned

- 1s – 1 byte signed
- 2u – 2 byte unsigned (little-endian order)
- 2s – 2 byte signed (little-endian order)
- 4f – float (IEEE-754 standard)
- 4s – 4 bytes signed (little-endian order)
- string – ASCII character array, first byte is array size
- Nb – byte array size N

- CMD\_ID – 1u
- INTERVAL\_MS – 2u
- CONFIG – 8b
- RESERVED – 10b

For each serial interface, only one unique combination of CMD\_ID + CONFIG bytes may be registered. If the data stream is already registered, it will be updated. To unregister it, specify INTERVAL\_MS=0. The total number of data streams over all serial interfaces is limited (for 2.59 ver. limit is 10)

If the data stream is successfully registered or updated, the CMD\_CONFIRM is sent in answer.

Take care of the serial bandwidth: if data flow exceeds bandwidth, particular samples may be skipped. The same is true when the TX buffer is full when sending long commands like CMD\_READ\_PARAMS\_3.

The interval is maintained with the +-1ms tolerance for the individual sample, but the averaged sample rate exactly matches to specified.

Meaning of the CONFIG bytes is specific for each command and is described in the 'Parameters' section.
